HiCareer

Workflow Automation Specialist

Dear HiCareer Team,

The stack in your job description — n8n, Make, Zapier, REST APIs, JSON, Claude API, OpenAI API — is not a list of tools I've experimented with. It is the exact stack I have been building production systems on for the past three years. I want to bring that to HiCareer as your Workflow Automation Specialist.

My flagship build is the CCM Enrollment Intelligence System, a workflow architecture I designed and deployed for a Medicare insurance operation with 300 live agents. The scope covered 11 integrated platforms — CRM, billing, telephony, compliance, and enrollment systems — all connected through REST APIs with structured JSON data flows, error handling, retry logic, and audit logging built into every node. I did not inherit this system. I scoped it from scratch: gathered requirements from operations, compliance, and training stakeholders; mapped the data flows; selected the right tool for each layer (n8n for core orchestration, Python for custom logic, Supabase/PostgreSQL for state); built and tested each integration; deployed to production; and owned the monitoring from there. That is the full lifecycle the role describes, and it is how I approach every automation I build.

The LLM integration layer is where the work gets interesting. For CCM, I built a real-time Claude API workflow that ingested live call transcripts, applied structured compliance prompts, parsed JSON responses, and routed guidance back to agents — all within the live call. Sub-second latency, zero failures, full audit trail. Through Jaws AI 911, I continue building multi-step LLM workflows using both Claude and OpenAI APIs: prompt chaining, conditional branching, structured output parsing, and automated fallback paths when inference returns unexpected responses.

Error handling and retry logic are not afterthoughts in my builds — they are part of the design spec. Every production workflow I deploy includes failure-mode mapping, structured event logs (not just success logs), and explicit retry behavior for external API calls. When something breaks at 2am, the workflow catches it, logs the context, retries with backoff, and alerts — it does not silently fail and leave corrupted data downstream.

The lifecycle ownership is the differentiator. Many automation candidates can configure a Make scenario from a template. I scope requirements, make architectural decisions, write the custom code that no-code tools cannot handle, deploy to production, and iterate based on monitoring data. That is the level of ownership I bring to every project.

I would welcome the chance to discuss specific automation challenges on your current roadmap and show you examples of the production workflows I have built.

Sincerely,

Bryan Jaworski
